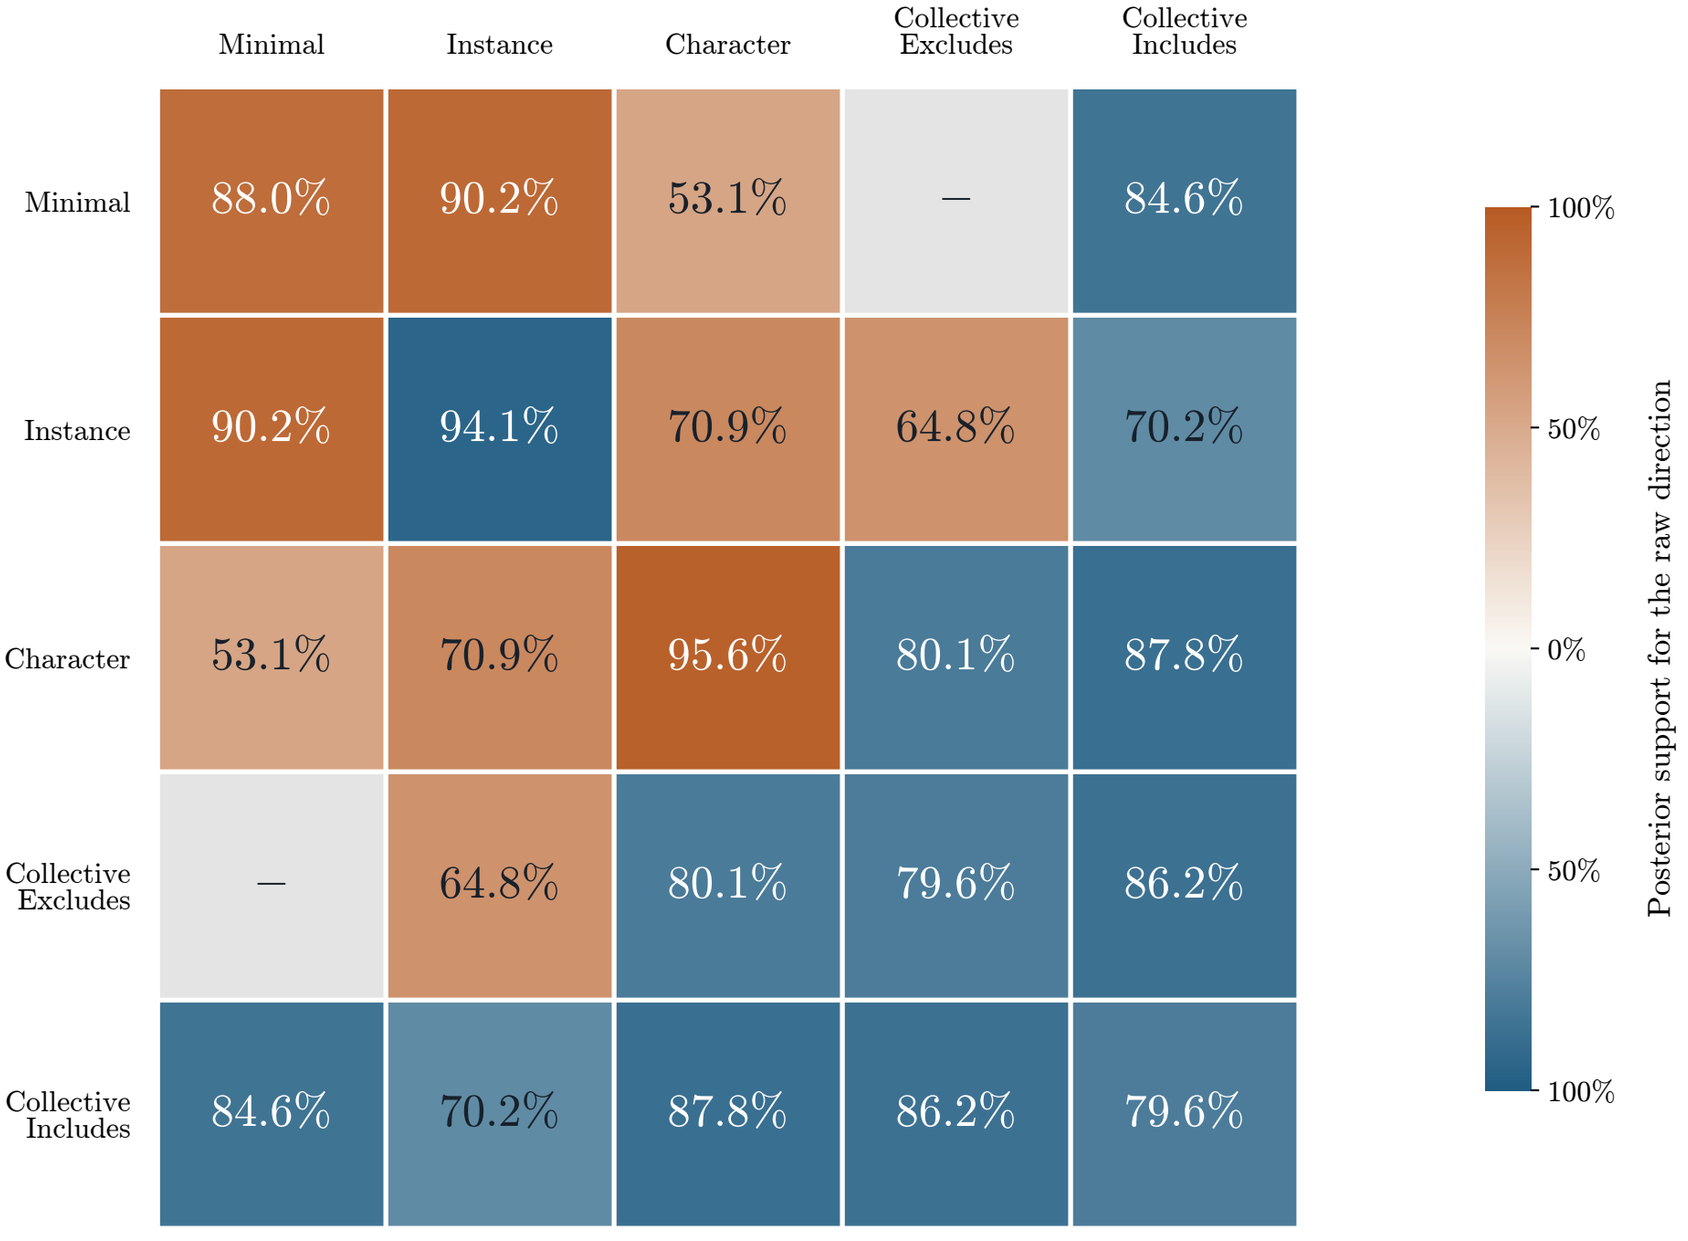
Posterior support for the observed direction

Threat — February single-agent reference

Jeffreys posteriors from counts; group and baseline uncertainty retained



15 distinct pairs; 25 groups per pair. Mirrored cells repeat the same result.

Blue: negative raw difference; orange: positive. Stronger colour means greater support.

Cell: $P(\Delta < 0 \mid D)$ if raw $\Delta < 0$; $P(\Delta > 0 \mid D)$ if raw $\Delta > 0$.

Grey / dash: exactly zero raw difference; no directional percentage is assigned.

Both Collective variants share one original Collective baseline parameter. Pool counts first.

Conditional on saved labels and model assumptions; historical comparisons do not isolate communication effects.

Support below 50% means the posterior favours the opposite direction from the raw estimate.
